- REV = { $\rho_{ij}: 1 \le i < j \le n$ }, where  $\rho_{ij}$  is the identity permutation where the chunk between positions *i* and *j* is reversed. <u>Ex</u>:  $\langle 14325 \rangle$  reverses the chunk from 2nd to 4th positions Distance induced: **reversals' distance** Valentino Santucci ECPERM Keynote @ GECCO 2020 8th July 2020 9/34

## Relations among the generating sets

- ASW is a proper subset of EXC, INS, REV
- INS  $\cap$  EXC = ASW
- INS  $\cap$  REV = ASW
- EXC  $\cap$  REV = ASW  $\cup \{\epsilon_{ij} \in$  EXC :  $|i j| = 2\}$
- $INS = INS_{bw} \cup INS_{fw}$
- $INS_{bw} \cap INS_{fw} = ASW$

## Relations among the generating sets

- ASW is a proper subset of EXC, INS, REV
- INS  $\cap$  EXC = ASW
- INS  $\cap$  REV = ASW
- EXC  $\cap$  REV = ASW  $\cup \{\epsilon_{ij} \in$  EXC :  $|i j| = 2\}$
- $INS = INS_{bw} \cup INS_{fw}$
- $INS_{bw} \cap INS_{fw} = ASW$
- Useful for:
  - Designing Variable Neighborhood Search algorithms
  - Designing perturbation step in Iterative Local Search algorithms
  - A priori smoothness estimation in Fitness Landscape Analysis

<日<br />
<</p>

## Properties of the generating sets

- Cardinality = number of neighbors
- Diameter of the Cayley graph (search space)
- Number of longest permutations (whose shortest-path distance from the identity equals the diameter)
- **Abstract convexity**: any permutation resides in a shortest path between the identity and a longest permutation?
- Lattice structure: meet and join are well defined?

GSet	Card.	Diameter	#Longest Perm.	Abst.Convex	Lattice
ASW	n-1	$\binom{n}{2}$	1	Yes	Yes
EXC	$\binom{n}{2}$	n-1	(n - 1)!	Yes	No
INS	$(n-1)^2$	n-1	1	No	No

(I) < (II) <

## Algebraic Framework for Permutations

Discrete operators for equations of motion in EAs

#### Let:

- ASW<sub>n</sub> = {σ<sub>1</sub>,...,σ<sub>n-1</sub>} be the "adjacent swap" generators of S<sub>n</sub>
  π, ρ ∈ S<sub>n</sub>
- $\langle \sigma_{i_1}, \ldots, \sigma_{i_k}, \ldots, \sigma_{i_l} \rangle$  be a minimal factorization of  $\pi$  whose length is l•  $a \in [0, 1]$

Discrete operators are defined as follows:

• 
$$\pi \oplus \rho := \pi \circ \rho$$

• 
$$\pi \ominus \rho := \rho^{-1} \circ \pi$$

•  $a \odot \pi := \sigma_{i_1} \circ \cdots \circ \sigma_{i_k}$ , with  $k = \lceil a \cdot l \rceil$ 

イロト 不得下 イヨト イヨト 二日

## Discrete sum and difference

• Algebraically, they do not rely on the chosen generating set

• They are deterministic

• They are consistent to each other:

$$\pi = 
ho \oplus (\pi \ominus 
ho) = 
ho \circ (
ho^{-1} \circ \pi) = \pi$$

## How much random we are?

- All the stochastic factorization algorithms perform a **random walk in the sub-graph** formed by the union of all the shortest paths from the identity to the permutation to factorize.
- **Cannot increase entropy** (over the set of minimal factorizations) without increasing computational complexity.

- Let  $\pi, \rho \in \mathcal{S}_n$  and  $a \geq 0$
- Let  $|\pi|$  be the length of a minimal factorization of  $\pi$
- Let  $\rho \sqsubseteq \pi$  iff a minimal factorization of  $\rho$  is a prefix of a minimal factorization of  $\pi$

・ 何 ト ・ ヨ ト ・ ヨ ト

- Let  $\pi, \rho \in \mathcal{S}_n$  and  $a \geq 0$
- Let  $|\pi|$  be the length of a minimal factorization of  $\pi$
- Let  $\rho \sqsubseteq \pi$  iff a minimal factorization of  $\rho$  is a prefix of a minimal factorization of  $\pi$
- $\rho = a \odot \pi$  has to satisfy:

$$\begin{array}{ll} (\mathsf{C1}) & |\rho| = \lceil a \cdot |\pi| \rceil \\ (\mathsf{C2}) & \text{if } a \in [0,1] \text{ then } \rho \sqsubseteq \pi \\ (\mathsf{C3}) & \text{if } a \ge 1 \text{ then } \pi \sqsubseteq \rho \end{array}$$

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

## Issues when a > 1

- Issue1:  $|a \odot \pi|$  may be larger than the diameter
- Motivation1: Search space is finite
- Solution1: Truncate if diameter is exceeded

(日) (四) (日) (日) (日)

### Issues when a > 1

- **Issue1**:  $|a \odot \pi|$  may be larger than the diameter
- Motivation1: Search space is finite
- Solution1: Truncate if diameter is exceeded
- Issue2: a ⊙ π may not exists for any π ∈ S<sub>n</sub> when INS is used (because of the non-convexity)
- Motivation2: *longest increasing subsequence* cannot always be reduced by *shifting away* an item
- Solution2: reverse, consider the longest decreasing subsequence, reverse again  $\implies$  it is like using a surrogate weight which is in (non-strict) monotonic relation with the INS weight

#### Bit-strings

Operator: xor

Generators: bit-strings with only one 1-bit

#### Integer vectors

Operator: +

Generators: vectors with all 0s except one  $\pm 1 \text{ entry}$ 

#### • Enumerable subset of real vectors

whose entries are "multiples" of a chosen constant  $\hbar > 0$  Operator: +

Generators: vectors with all 0s except one  $\pm\hbar$  entry

Pushing  $\hbar \to 0$  tends to replicate the continuous behaviour in discretized equations of motion

## Properties of $\oplus, \ominus, \odot$

Properties which are satisfied:
 (X is the discrete set of solutions, e.g. permutations)

(i) 
$$\oplus$$
 is associative;  
(ii)  $\oplus$  is commutative iff  $\circ$  is commutative;  
(iii)  $e$  is the neutral element for  $\oplus$ ;  
(iv)  $x \oplus x^{-1} = x^{-1} \oplus x = e$  for each  $x \in X$ ;  
(v)  $1 \odot x = x$  for each  $x \in X$ ;  
(vi)  $a \odot (b \odot x) = (ab) \odot x$  for each  $x \in X$  and  $a, b \ge 0$ ;  
(vii)  $0 \odot x = e$  for each  $x \in X$ ;  
(viii)  $x \oplus (y \ominus x) = y$  for each  $x, y \in X$ .

• Distributive properties are missing

$$w \odot \nu \neq [(1+w) \odot \nu] \ominus \nu$$

where  $w \ge 0$  and  $\nu \in S_n$ . Caution on PSO inertial term

Valentino Santucci

- Permutation as a set of precedences: iteratively construct a permutation precedence by precedence (Baioletti et al., 2017; Santucci & Ceberio, 2020)
- Cycle structure: interesting for TSP and VRP (future work)

# ... but is it working?

- ADE and APSO significantly outperform the naive DE and PSO equipped with the popular random-key decoder on a variety of benchmarks (Santucci, Baioletti, & Milani, 2019; Santucci et al., 2020)
- ADE obtained:
  - state-of-the-art results on the PFSP, LOPCC and MDTWNPP (Baioletti et al., 2020b; Santucci et al., 2016; Santucci, Baioletti, Di Bari, et al., 2019)
  - competitive results on the LOP, TSP and SRLFP (Baioletti et al., 2015; Baioletti, Milani, Santucci, & Bartoccini, 2019; Di Bari et al., 2020)
  - peak results among EAs for Bayesian networks learning (Baioletti et al., 2018b)
- Algebraic crossovers are competitive with classical permutation crossover operators (Baioletti et al., 2018a)
- Representation as set of precedences allowed to obtain state-of-the-art results on the LOP (Santucci & Ceberio, 2020)
- Identify preferred pairs of items to exchange in order to exit basins of attraction of QAP instances (Baioletti, Milani, Santucci, & Tomassini, 2019)

ECPERM Keynote @ GECCO 2020

# Conclusions and Open Questions

- The rich algebraic structure of permutations can be fruitfully exploited for:
  - Study structure and properties of the search space
  - Designing algorithms and operators in EC
  - Study the search behaviour of an algorithm

# Conclusions and Open Questions

- The rich algebraic structure of permutations can be fruitfully exploited for:
  - Study structure and properties of the search space
  - Designing algorithms and operators in EC
  - Study the search behaviour of an algorithm

#### Open questions:

- Can algebraic properties be used to derive expected runtime analyses?
- Can algebraic properties be used to build a tunable instance generator for the permutation space?
- Is a review article about EC for permutation problems useful to the community? :-)
